

Experiment: DNS Lookup using Python

Aim

To resolve a domain name into its corresponding IP address using Python's socket module.

Algorithm:

1. Import the socket module.
2. Read the domain name from the user.
3. Use the socket.gethostbyname() function to resolve the domain name.
4. If the domain exists, display its IP address.
5. If the domain cannot be resolved, display an error message.

Python Code:

```
import socket
```

```
domain = input("Enter Domain: ")
```

```
try:
```

```
    ip = socket.gethostbyname(domain)
```

```
    print("IP Address:", ip)
```

```
except:
```

```
    print("Unable to resolve domain.")
```

Sample Input 1

Enter Domain: google.com

Sample Output 1

IP Address: 142.250.182.14
