

Phishing Email Detector using Python

Aim

To detect whether an email is suspicious by checking the sender email, subject, and body for common phishing indicators.

Algorithm

1. Read the sender email, subject, and email body from the user.
2. Store common phishing keywords in a list.
3. Initialize the phishing score to 0.
4. Check whether the sender belongs to a trusted domain (gmail.com or outlook.com). If not, increment the score.
5. Search the subject for phishing keywords and increase the score for each match.
6. Search the email body for phishing keywords and increase the score for each match.
7. Display the phishing score.
8. If the score is 3 or more, classify the email as suspicious; otherwise, classify it as safe.

Python Code

```
sender = input("Enter Sender Email: ")
subject = input("Enter Subject: ")
body = input("Enter Email Body: ")
```

```
keywords = [
    "urgent", "verify", "password",
    "bank", "click", "winner",
    "lottery", "login", "account"
]
```

```
score = 0
```

```
if "@gmail.com" not in sender and "@outlook.com" not in sender:
    score += 1
```

```
for word in keywords:
    if word.lower() in subject.lower():
        score += 1
```

```
for word in keywords:
    if word.lower() in body.lower():
        score += 1

print("\nPhishing Score:", score)

if score >= 3:
    print("Suspicious Email (Possible Phishing)")
else:
    print("Looks Safe")
```

Sample Input

Enter Sender Email: support@securebank.com

Enter Subject: Urgent! Verify Your Bank Account

Enter Email Body: Click here to verify your password and login.

Sample Output

Phishing Score: 7

Suspicious Email (Possible Phishing)
